# I

## MOTIVATION

- ▶ Hubble tension:  $H_{0,P18} = 67.36 \pm 0.54$  km/s/Mpc [Aghanim et al., 2022] vs.  $H_{0,late} = 73.3 \pm 0.8$  km/s/Mpc [Verde et al., 2019] from  $z \lesssim 2$ .  
 $H_{0,late} = 66.6^{+4.4}_{-3.3}$  km/s/Mpc from Refsdal's reappearance. (2305.06367)
- ▶  ${}^7\text{Li}$  Problem in BBN: the abundance ratio  ${}^7\text{Li}/\text{H} \times 10^{10} : 1.6 \pm 0.3$  (observed) vs.  $5.6 \pm 0.3$  (theoretical) [Zyla et al. 2020, Pitrou et al., 2018, Iliadis and Coc, 2020].
- ▶ The weak lensing measurement of  $S_8$  together with the clustering parameter  $\sigma_8$  [Troxel et al., 2018] yields a value smaller  $S_{8,DES} = 0.773^{+0.026}_{-0.020}$  than given by the CMB- $\Lambda$ CDM value,  $S_{8,CMB} = 0.832 \pm 0.013$ .
- ▶ Isotropic cosmic birefringence angle based on the cross-power (parity-violating)  $C_l^{EB}$  data in CMB [Minami and Komatsu, 2020], deviate from 0 by  $\sim 2.4\sigma$ .  
Later improved result: deviate from 0 by  $\sim 3.6\sigma$  [Eskilt and Komatsu, 2022].

## II

# SOLUTIONS

A Higher Higgs VEV during the BBN epoch.

- ▶ Fermi constant  $G_F \propto v^{-2}$ . A smaller  $G_F$  leads to an earlier freeze out of the  $n \rightleftharpoons p$  and a longer  $n$  lifetime.

A larger  $n$  density than that in the standard BBN.

- ▶ Electro mass  $m_e \propto v$ . A larger  $m_e$  will reduce the rate of  $n \rightleftharpoons p$  and delay neutron decay.
- ▶ Mass difference  $\Delta m_q = m_d - m_u \propto v$ , which contributes to  $\Delta m_{np}$  and impact  $n \rightleftharpoons p$  and neutron decay oppositely relative to  $G_F$  and  $m_e$ .
- ▶ Averaged light quark mass, which contributes to pion mass  $m_\pi$ . A larger pion mass makes nuclei less tightly bound. The nuclear-reaction rates thus may change substantially.

An upward variance of  $\nu$  will

- ▶ reduce the primordial mass fraction of Helium-4,  $Y_p$ ,
- ▶ raise the Deuterium primordial abundance  $D/H$  relative to Hydrogen.

The current experimental bounds on  $Y_p$  and  $D/H$  are still compatible for  $\delta\nu_{\text{BBN}} \sim \mathcal{O}(1\%)$  and  $\delta\eta \sim \mathcal{O}(1\%)$  (**CMB baryon-to-photon ratio**).

Following this, to addressing the  ${}^7\text{Li}$  problem, one needs [[Pitrou et al. 2018](#)]

$$\delta\nu_{\text{BBN}} = (1.1 \pm 0.1)\% , \quad \delta\eta = (1.7 \pm 1.3)\% .$$

Focus on the model  $\Lambda\text{CDM}+m_e$ . [Hart and Chluba, 2019]

$$\delta m_e \approx \delta v_{\text{rec}} \sim 1\%.$$

- ▶ Thompson scattering cross-section,  $\sigma_T \propto m_e^{-2}$ .
- ▶ The atomic energy levels,  $E_i \propto m_e$ .
- ▶ ...

$\Rightarrow$  Shift up the redshift of the rec  $z_*$ , and the baryon drag redshift  $z_d$ .

$\Rightarrow$  Sound horizon at rec decrease.

$\Rightarrow$  To keep angular sound horizon at rec unchanged,  $H_0$  increases.

Figure:  $BM_1$ :  $\delta v = 1.1\%$ .  $BM_2$ :  $\delta v = 1.0\%$ .  $BM_3$ :  $\delta v = 0\%$ .  $BM_{BBN}$ :  $\delta v = \delta v_{BBN}$ .

Introduce the ultra-light axion-like particle,  $\omega_a$ .

Consider the axion-photon coupling  $aF\tilde{F}$ . [Carroll and Field, 1990]

$$\mathcal{L} \supset \frac{1}{32\pi^2} \frac{a}{f_a} F_{\mu\nu} \tilde{F}^{\mu\nu}$$

$$\Rightarrow \beta_{\text{obs}} \sim \frac{1}{16\pi^2} \frac{a_{\text{ini}}}{f_a}$$

$$\Rightarrow \frac{a_{\text{ini}}}{f_a} \approx 1.0 \pm 0.3$$

## III

## A(-XION) SOLUTION

- ▶ An up-shift of electron mass at the recombination era  $\delta m_e \sim 1\%$  could resolve Hubble tension. [Hart & Chluba (2020)]
- ▶  $^7\text{Li}$  problem could be solved by lifting the Higgs VEV  $\delta v \sim 1\%$ . [2102.11257 and refs therein]
- ▶ Ultra light axion could be used to explain ICB. [Minami & Komatsu (2020)]
- ▶ Introducing the ultra-light axion may be helpful suppressing the  $S_8/\sigma_8$ . [KiDS-450 (2017), Handley & Lemos (2019)]

A model with evolving Higgs VEV and the axion?

**Axi-Higgs is constructed by introducing coupling between ultra-light axion(s) and the Higgs.**

# Axi-Higgs Potential

Axi-Higgs  
Cosmology

Yu-Cheng QIU

Motivation

Solutions

A(-xion) Solution

Summary and  
Outlook

Scalar potential is  $V = V_a + V_\phi$ , where

$$V_a = m_a^2 f_a^2 \left( 1 - \cos \frac{a}{f_a} \right) \approx \frac{1}{2} m_a^2 a^2 - \frac{1}{24} \frac{m_a^2}{f_a^2} a^4 + \dots ,$$

$$V_\phi = \left| m_s^2 F(a) - \kappa \phi^\dagger \phi \right|^2 , \quad F(a) = 1 + \frac{C a^2}{M_{\text{Pl}}^2} .$$

Neglect three Goldstone directions and let  $\phi^\dagger \phi \rightarrow v^2/2$ , then

$$V \approx \frac{1}{2} m_a^2 a^2 + |B(a, v)|^2 , \quad B = m_s^2 \left( 1 + \frac{C a^2}{M_{\text{Pl}}^2} \right) - \frac{1}{2} \kappa v^2 .$$

Treating  $a(t)$  as a background field, the Higgs VEV is given by minimize  $\langle V_\phi \rangle$ , which is

$$\langle \phi^\dagger \phi \rangle \equiv \frac{v^2}{2} = \frac{m_s^2}{\kappa} F(a)$$

- ▶  $m_a \sim 10^{-29} \text{ eV} \implies a(t)$  evolves in the cosmic time scale.
- ▶ Higgs VEV  $v(a(t))$  also evolves in the cosmic time scale,

$$\delta v(t) = \frac{v(t) - v_0}{v_0} = [F(a(t))]^{1/2} - 1 \simeq \frac{Ca(t)^2}{2M_{\text{Pl}}^2},$$

where  $v_0 = \sqrt{2}m_s/\sqrt{\kappa} = 246 \text{ GeV}$ .

- ▶  $a(t)$  is determined by KG equation in the FLRW background,

$$\ddot{a} + 3H(t)\dot{a} + \frac{\partial V_a}{\partial a} = 0.$$

**Evolving Higgs VEV is driven by misalignment mechanism of the ultra-light axion.**

One may worry about the back reaction from the Higgs to the axion.

Consider the coupled EoMs for  $a(t)$  and  $v(t)$ ,

$$\ddot{a} + 3H\dot{a} + \left[ m_a^2 + \frac{4Cm_s^2}{M_{\text{Pl}}^2} B(a, v) \right] a \approx 0$$
$$\ddot{v} + (3H + \Gamma_\phi) \dot{v} - 2\kappa B(a, v)v = 0 ,$$

where  $\Gamma_\phi \sim 4 \text{ MeV}$  is effective Higgs field dissipation.

- ▶ At first sight,  $m_s^2 B / M_{\text{Pl}}^2 \sim 10^{50} m_a^2$  and second term in potential driven force dominated over  $m_a$ . Fortunately, this is not the case.
- ▶ Thanks to the presence of  $\Gamma_\phi$ , Higgs field profile got damped quickly to the value where  $B(a, v) = 0$ .

**The coupled system will evolve along the valley in  $a$ - $\phi$  configuration space.**

Motivation

Solutions

A(-xion) Solution

Summary and  
Outlook

$$\begin{aligned}\delta v(t) &= \frac{Ca(t)^2}{2M_{\text{Pl}}^2} \\ &= \delta v_{\text{ini}} \frac{a(t)^2}{a_{\text{ini}}^2}\end{aligned}$$

Set  $\delta v_{\text{ini}} = 1\%$ .

- ▶ One has two bounds on the axion mass.
  1. Keep  $\delta v \geq 1\%$  until  $t \gtrsim t_{\text{rec}}$ .
  2.  $d(\delta v)/dt \lesssim 10^{-16} \text{ yr}^{-1}$  required by experimental bound.

This leads to

$$1.0 \lesssim \frac{m_a}{10^{-29} \text{ eV}} \lesssim 3.3, \quad 68\% \text{ C.L.}$$

- ▶ ICB determines  $a_{\text{ini}}/f_a \approx 1$ .
- ▶ Suppose  $a$  takes up  $x$  fraction of today's matter energy density and one could constrain  $a_{\text{ini}}$ .

Numerically, parameters are

$$a_{\text{ini}} \approx 3.7 \times 10^{17} \text{ GeV} \left( \frac{x}{0.01} \right)^{1/2} \left( \frac{\xi}{1.5} \right)^{-1},$$

$$f_a \approx 3.8 \times 10^{17} \text{ GeV} \left( \frac{x}{0.01} \right)^{1/2} \left( \frac{\xi}{1.5} \right)^{-1},$$

$$C \approx 0.84 \left( \frac{\delta v_{\text{ini}}}{0.01} \right) \left( \frac{x}{0.01} \right)^{-1} \left( \frac{\xi}{1.5} \right)^2,$$

where  $x = \omega_a / (\omega_a + \omega_b + \omega_c)$ ,

and  $\xi$  is the numerical factor from equation  $\xi H(z_a) = m_a$ .

Be aware that  $m_a$  does not come in above parameters.

There are four parameters in the single axion axi-Higgs model,

$$m_a, \delta v_{\text{ini}}, a_{\text{ini}}, f_a$$

which are all relatively well-constrained.

- ▶  $\delta v_{\text{BBN}} \approx \delta v_{\text{rec}} > \delta v_0 = 0 \implies m_a \approx 10^{-30} \text{ eV} - 10^{-29} \text{ eV}$
- ▶  ${}^7\text{Li}$  and  $H_0$  puzzle  $\implies \delta v_{\text{ini}} \approx 1\%$
- ▶  $H_0$  tension &  $S_8/\sigma_8$  tension  $\implies a_{\text{ini}} \approx 10^{17} \text{ GeV}$
- ▶ CMB Birefringence  $\implies f_a \approx a_{\text{ini}} \approx 10^{17} \text{ GeV}$

A(-xion) Solution

Summary and  
Outlook

# Two-axion Axi-Higgs

Axi-Higgs  
Cosmology

Yu-Cheng QIU

Motivation

Solutions

A(-xion) Solution

Summary and  
Outlook

- ▶ As the evolution of single-axion, one would expect that  $\delta v_{\text{BBN}} > \delta v_{\text{rec}}$ .
- ▶ To better resolve Hubble tension, one would require  $\delta v_{\text{rec}} > 1\%$ . Meanwhile, BBN analysis prefers  $\delta v_{\text{BBN}} < 1.1\%$ .
- ▶ In fuzzy dark matter scenario, an axion with mass  $\sim 10^{-22}$  eV as the cold dark matter can resolve a number of problems in the weakly interacting massive particle (WIMP) model.
- ▶ A second axion could naturally appear in function  $F$  that actually responsible for Higgs VEV.

Consider two axions with mass  $m_1 = 10^{-29}$  eV and  $m_2 = 10^{-22}$  eV. Neglecting interaction between  $a_1$  and  $a_2$ , function  $F$  is given by

$$F(a_1, a_2) = 1 + \frac{C_1 a_1^2}{M_{\text{Pl}}^2} + \frac{C_2 a_2^2}{M_{\text{Pl}}^2}.$$

We expect small deviation of Higgs VEV, which could be approximated by

$$\delta v(t) = F^{1/2} - 1 \approx \frac{C_1 a_1^2}{2M_{\text{Pl}}^2} + \frac{C_2 a_2^2}{2M_{\text{Pl}}^2}.$$

- ▶  $a_{1,\text{ini}}$  the same as single-axion case. Consider  $a_{2,\text{ini}}$  consists of most of the dark matter and it starts to roll down at  $z_2 \sim 2 \times 10^6$ , one has

$$a_{1,\text{ini}} \approx 3.7 \times 10^{17} \text{ GeV} , \quad a_{2,\text{ini}} \approx 1.5 \times 10^{17} \text{ GeV} .$$

- ▶  $C_{1,2}$  are determined by

$$\frac{C_1 a_{1,\text{ini}}^2}{2M_{\text{Pl}}^2} + \frac{C_2 a_{2,\text{ini}}^2}{2M_{\text{Pl}}^2} = \delta v_{\text{BBN}} , \quad \frac{C_1 a_1^2(t_{\text{rec}})}{2M_{\text{Pl}}^2} = \delta v_{\text{rec}} .$$

For  $\delta v_{\text{BBN}} = 1\%$ ,  $\delta v_{\text{rec}} = 2\%$  and relation  $a_1(t_{\text{rec}}) \approx 0.99 a_{1,\text{ini}}$ ,

$$C_1 \approx 1.7 , \quad C_2 \approx -5.1 .$$

# IV

## SUMMARY

- ▶ Axi-Higgs model introduces an evolving Higgs VEV using  $|\dots|^2$ .
- ▶ This form  $|\dots|^2$  ensures the cosmic evolution of  $v$  and protects the axion evolution from the Higgs back-reaction.
- ▶ A slightly higher  $v$  in the early universe helps resolve Hubble tension and  ${}^7\text{Li}$  problem.
- ▶ The introduction of axion helps explain the ICB and suppress  $S_8/\sigma_8$ .
- ▶ The parameters are tightly constrained and could be tested in the near future.

Thank you for your attention.

- Consider  $X^2 = 0$  with  $X = x + \sqrt{2}\theta G + \theta^2 F^X$ .

$$x^2, \quad xG_\alpha = 0, \quad 2xF^X - GG = 0 \quad \implies \quad X = \frac{GG}{2F^X} + \sqrt{2}\theta G + \theta^2 F^X.$$

- For  $X^2 = XQ = 0$  with  $Q = q + \sqrt{2}\theta\phi + \theta^2 F^Q$ ,

$$x = \frac{GG}{2F^X}, \quad xq = 0, \quad qG_\alpha + x\psi_\alpha = 0, \quad qF^X + xF^Q - G\psi = 0$$

$$\implies \quad q = \frac{1}{F^X} \left( \psi - \frac{F^Q G}{2F^X} \right) G$$

- $\bar{D}_{\dot{\alpha}}(X\bar{Z}) = X^2 = 0$  with  $Z = z + \sqrt{2}\theta\chi + \theta^2 F^Z$  gives

$$\chi = i\partial_\mu z \sigma^\mu \frac{\bar{G}}{\bar{F}^X}$$

$$F^Z = -\partial_\mu \left( \frac{\bar{G}}{\bar{F}^X} \right) \bar{\sigma}^\nu \sigma^\mu \frac{\bar{G}}{\bar{F}^X} \partial_\nu z + \frac{\bar{G}\bar{G}}{2(\bar{F}^X)^2} \partial^2 z$$

The axi-Higgs mass matrix is given by

$$\mathbf{M} = \begin{pmatrix} m_a^2 + \frac{8m_s^4 a^2}{M_{\text{Pl}}^4} & -\frac{2\sqrt{2}m_s^2 a v}{M_{\text{Pl}}^2} \\ -\frac{2\sqrt{2}m_s^2 a v}{M_{\text{Pl}}^2} & v^2 \end{pmatrix}, \quad \lim_{m_a \rightarrow 0} \det \mathbf{M} = 0$$

Diagonalize  $\mathbf{M}$ , one has

$$\left(m_\phi^{\text{phys}}\right)^2 \approx 4m_s^2 \left(1 + \frac{a^2}{M_{\text{Pl}}^2}\right) + \mathcal{O}(m_a^2)$$

$$\left(m_a^{\text{phys}}\right)^2 \approx m_a^2 + \mathcal{O}(m_a^4)$$

- Above the scale  $\sqrt{m_a f_a}$ , the shift symmetry of axion is restored.

$$\Delta m_a^2 \sim \frac{1}{\pi^2} \left(\frac{m_s^2}{M_{\text{Pl}}^2}\right) \left(\frac{m_a^2 f_a^2}{m_\phi^2}\right) \lesssim m_a^2$$

Spontaneous SUSY-breaking by  $\overline{D3}$ -brane could be described by a nonlinear supergravity model. [Kallosh & Wrase (2014)]

$$K = X^\dagger X + \dots, \quad W = MX + \dots, \quad \underbrace{X^2 = 0}_{\text{nilpotent condition}}$$

The nilpotent condition projects out the scalar part of  $X$ ,

$$X = \frac{GG}{2F^X} + \sqrt{2}\theta G + \theta^2 F^X.$$

The  $X$  contributes to the scalar potential as

$$V_X = |M|^2$$

Nilpotent superfield  $X$  could be used as projector to eliminate d.o.f.s in other superfields. [Lindstorm & Rocek (1979), Komargodski & Seiberg (2009), Dall'Agata & Farakos (2016)]

- ▶  $XQ = 0$  projects out scalar part of  $Q$
- ▶  $XQ = \text{chiral}$  projects out fermionic d.o.f. of  $Q$ .
- ▶ ...

Higgs d.o.f are projected out to properly explain the cosmological constant problem. [Li, Qiu and Tye 2010.10089]

$$\begin{aligned} H_u H_d &\rightarrow \phi^\dagger \phi \\ \langle V_\mu \rangle + \langle V_D \rangle &\rightarrow 0 \end{aligned}$$

# The axi-Higgs coupling

Axi-Higgs  
Cosmology

Yu-Cheng QIU

Recall superpotential  $W \supset X (\tilde{m}_s^2 + \tilde{\gamma} H_u H_d)$ , where parameter  $\tilde{m}_s$  and  $\tilde{\gamma}$  is in principle determined by geometric sector  $(U_i, S)$ , which intrinsically include axion-like fields. Thus, it is natural to introduce

$$V_X \rightarrow \left| m_s^2 G(a) - \kappa K(a) \phi^\dagger \phi \right|^2 = \left| K(a) \left[ m_s^2 F(a) - \kappa \phi^\dagger \phi \right] \right|^2,$$

where  $G(a=0) = K(a=0) = 1$ ,

$$G(a) = 1 + \frac{ga^2}{M_{\text{Pl}}^2}, \quad K(a) = 1 + \frac{ka^2}{M_{\text{Pl}}^2}, \quad F(a) = \frac{G(a)}{K(a)} \approx 1 + \frac{Ca^2}{M_{\text{Pl}}^2},$$

and  $C = g - k$  is a constant whose positivity is undetermined.

$K(a)$  is not important. Let  $K(a) = 1$ .
